

Can we trust the training report?

A field guide to EduWork DataBridge

A training report may begin with four exports: an employee roster, learning events, assessment results, and credential awards. The final spreadsheet can look tidy even when IDs are missing, dates disagree, or two accounts may belong to the same person.

EduWork DataBridge is an open-source platform for keeping those decisions visible. It preserves source evidence, applies versioned mappings and validation rules, sends uncertain identity matches to review, and carries lineage into governed outputs.

Public examples use deterministic synthetic data. They do not describe a customer deployment or measured business outcome.

The Monday-morning question

Who completed cybersecurity training, passed the assessment, and received the credential?

HR knows the employee. The LMS knows the assignment and completion. The assessment system knows the score. The credential system knows the award. Someone still has to decide how those records fit together.

The project gives that reasoning a place to live. A missing ID becomes a named exception. A date conflict becomes a review item. A likely match carries evidence instead of becoming a silent merge.

The five-stop evidence path

- **Collect:** read approved source data and preserve an immutable, checksummed snapshot.
- **Check:** profile structure and run explicit validation rules.
- **Connect:** link identities with trusted IDs first and route gray-zone cases to review.
- **Publish:** create documented, permission-aware marts and masked exports.
- **Trace:** follow a report field back through the output, rule, and raw source.

The public case file

The small fixture contains 120 fictional HRIS people, 366 learning events, 120 assessment results, and 25 credential awards. It includes 43 deliberately planted problem occurrences across nine issue types.

Examples include nine missing employee IDs, seven invalid completion statuses, five completions before assignment, six duplicate LMS accounts, and one credential that predates its qualifying assessment.

What v0.20 adds

The match-review queue turns isolated decisions into a manageable workload. Authorized reviewers can list candidate pairs, filter by current status, page through the queue, inspect the latest decision and its history count, and see how many candidates have not yet been reviewed.

The queue is organization-scoped and permission-gated. It exposes record keys, safe evidence fingerprints, scores, statuses, and decision metadata without copying source records into the response.

The contribution

DataBridge makes cross-system data work inspectable. It treats the pipeline as a chain of evidence, gives bad records an explicit review path, and keeps uncertain identity decisions reversible. Governance travels with the output through checksums, dictionaries, lineage, permissions, audit events, and retention metadata.

The project also models restraint. It does not turn a probability into a fact or use synthetic results as a stand-in for customer outcomes.

Why it matters to organizations

- **Less spreadsheet ambiguity:** rules and exceptions are named instead of buried in formulas.
- **Faster review:** teams can see outstanding identity work and prioritize the cases that need attention.
- **Defensible reporting:** lineage and checksums connect a published answer to its source evidence.
- **Reusable controls:** mappings, validation rules, permissions, and retention metadata travel with the workflow.

How to evaluate it

Run the synthetic example locally, inspect the reviewer desk, then compare one recurring internal report with its current manual process. Useful measures include preparation time, exception rate, reviewer workload, correction history, and the ability to trace a published field without calling the pipeline author.

Responsible use

A real deployment must supply organization-specific ownership, mappings, identity rules, infrastructure validation, privacy review, and measured process findings. Public examples use synthetic data and do not establish customer adoption, certification, savings, or outcomes.

The software prepares evidence. People remain responsible for consequential decisions.
